

THREE MOST DISTANT PAIRS — each method's BEST case

all three libraries built at the SAME fixed 100-reaction budget · T = Tanimoto on the mode metric (Morgan r=3 / 2048)
the shared core (MCS) is haloed in red — what stays black is what actually differs

How far apart can each method reach at all? All three arms get to comparably distant pairs, so the libraries do not differ in reach -- they differ in the redundancy they tolerate, which is what the companion figure shows.
