

What does each filter buy? Removing one is the permissive end of its own knob

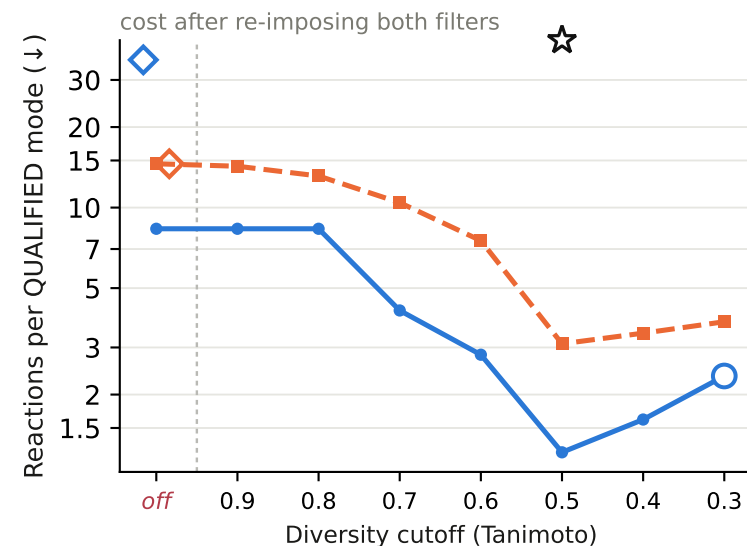

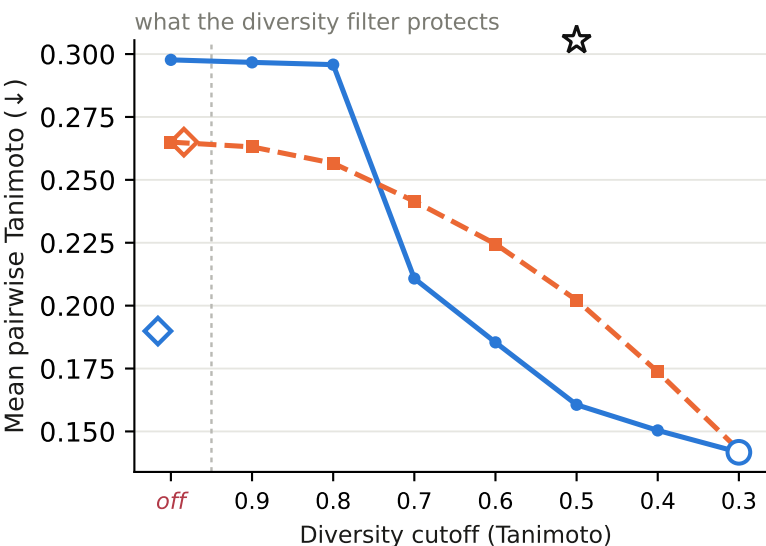

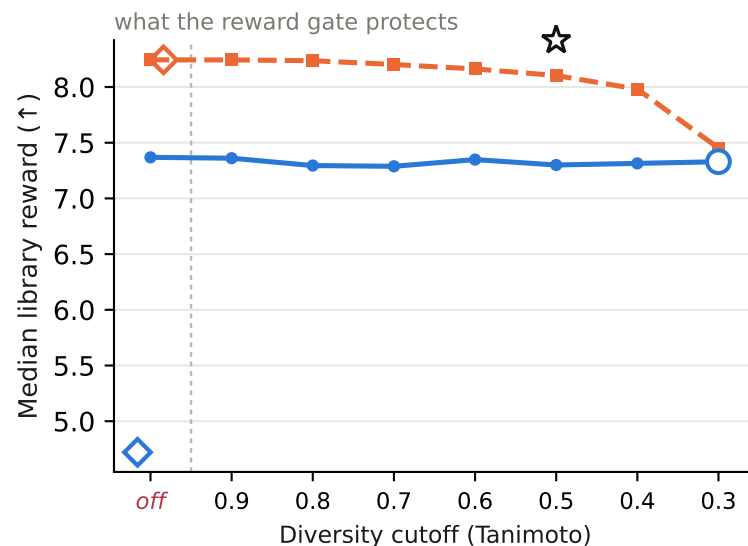

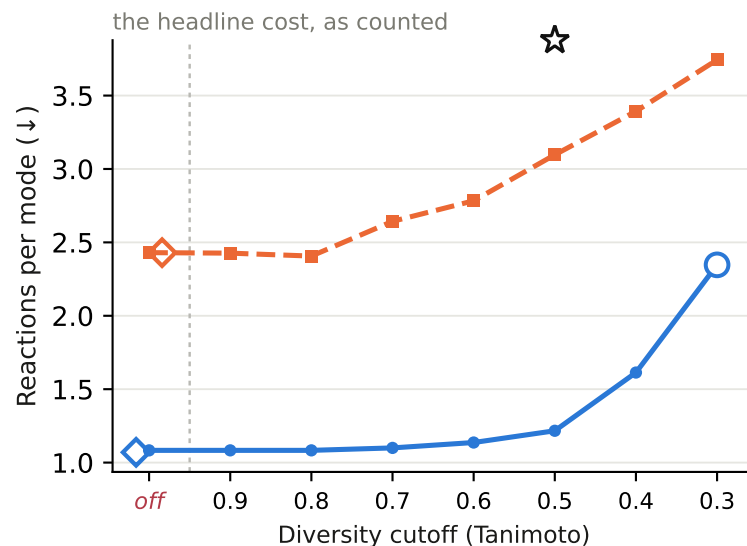

SCENT sEH surrogate — every arm delivers a 300-molecule library (matched size); ★ = the headline operating point ($\tau=7$, cutoff=0.5)

Hub batching Best candidate (previous) Both filters off Pool-limited

Reward filter ablated

Diversity filter ablated

"off" (left of the rule) = that filter removed; the other filter stays at the operating point. A QUALIFIED mode is a delivered molecule that survives the canonical definition (reward ≥ 7 AND Tanimoto ≤ 0.5 vs every mode kept), so the rightmost column is what each library really costs per molecule worth keeping. Hollow points are pool-limited (that library is smaller than every other cell's, so its cost is measured over a shorter run and is not comparable).
